Notes for week 3

- functions

def creates a function

calling it ~~calls~~ runs it, defining doesnt

return gives a value back out

print only shows something

catch it: total = add_tax(100)

docstring says what it does

help(name) shows the docstring

parameters and arguments

parameters pass values in

matched by position

default value is a fallback

keyword args: name which one you fill

positional first, keyword after

defaults come last in the def line

*args = extra values in a tuple

**kwargs = extra keywords in a dict

- scope

local means only exists inside it

using it outside = NameError

can read outer variables not change them

return the new value and reassign it

return a, b gives more than one value

unpack in order: x, y = f()

modules

import brings in a whole module

use a dot: math.sqrt(16)

math: sqrt pi ceil floor

random: randint(1, 6) choice()

from math import sqrt means no dot

math and random come with python

pandas needs pip install first

a module is a file of functions

__name__ == "__main__" only runs

when the file is run directly

maths typo = ModuleNotFoundError
